

Mini-Project (Fake Job offer detection)

Students Name: Pranav Tripathi and Varchasva Vikram Singh

Roll Numbers: 2401010129 and 2401010290

Course: Btech CSE Core (Semester 2)

Section: D

The Fake Job Offer Analyzer is a lightweight, browser-based tool designed to help users instantly vet incoming job offers for common scam indicators. Built entirely with standard web technologies—HTML for structure, CSS for a modern dark-themed aesthetic, and vanilla JavaScript for client-side logic—it requires no server backend or user registration.

At its core, the application presents a simple, intuitive interface: a large text area for pasting the body of any job offer email, and a single “Analyse Offer” button. When clicked, the script normalizes the input to lowercase and scans it against a curated list of suspicious keywords and phrases—everything from “no interview” and “quick money” to “passport needed,” “investment needed,” and “send money first.” If any red-flag terms are detected, the result panel immediately switches to a warning state (styled with a pulsating red glow) and enumerates each matched phrase. If none are found, the panel turns a reassuring green and proclaims the offer “appears safe.”

Because all processing happens entirely in the browser, scanning is instantaneous and private: user text never leaves the device. The clean Poppins-font layout, clear color cues, and focus-friendly controls ensure an accessible experience for both desktop and mobile users.

Looking ahead, this foundation could be extended with regex-based word-boundary matching to reduce false positives, inline highlighting of flagged terms, or an optional cloud-based API for more sophisticated machine-learning detection. But even in its current form, the Fake Job Offer Analyzer empowers job seekers to make smarter, safer decisions in just a few seconds—no IT expertise required.
